

HOW TO SELECT BEST LCD TV

LG
Life's Good

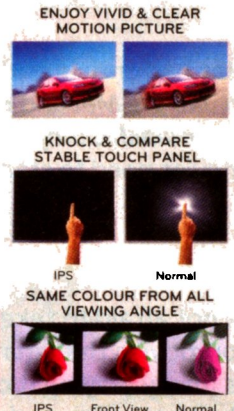

IPS (In Plane Switching) panel technology is one of the most leading and advanced LCD panel technologies in the world.

IPS panel technology innovatively aligns liquid crystal horizontally to increase the viewing angle and changes the LCD transmittance. IPS is mainly owned by the LG Display Company. This panel technology was unanimously accepted in its early phase by professionals from all across the globe.

Developed in 1996, IPS was initially meant to improve the poor viewing angle and the poor color reproduction of twisted nematic (TN) panels at that time. With the improved traditional TN panels, two technologies have been gained, one is VA (Vertical alignment) panel and the other is IPS one.

The viewing angle of the IPS panel is thus much better, mainly as it can ensure the proportion of the 3 colours within a large visible

is interrupted with the side dim pictures of the VA LCD TV. For the colour shift, the pictures are so dim, being watched from the sides affecting the quality. However, being different from the one of the VA LCD, with the unique horizontal molecule transfer technology, the IPS LCD has solved the problem of colour shift. The perfect picture quality has been ensured no matter from which side to be watched. Hence, in comparison with the VA one, the IPS LCD is more suitable for enjoyment shared with family, having terminated the history that the matches could not be enjoyed together with family or friends. Thanks to IPS LCDs that watching IPL has become a superior viewing experience. With World Cup and Commonwealth Games round the corner, give your eyes a finer and healthier viewing experience with IPS technology!

range. With brightness and contrast reduced to some extent, the colours will not be affected. More importantly, its layers are ideal. With contrast reduced, the colour definition is perfect, which cannot be realized by a VA panel.

Knock the panel- IPS stand out! A VA panel makes the light transmitted by switching the liquid crystal molecules. So, by knocking the panel, the molecules are compressed to become distorted to leak the light. The IPS panel is hard. Its molecular arrangement is not changed remarkably by being knocked. When the IPS panel is pressed down, the original colours remain, with some change of brightness.

IPS enabled LCD TV particularly deserves praise on its dynamic image expression in comparison to a normal LCD TV, because the IPS liquid crystal responds faster and expresses smoother moving images. While ensuring the image sharpness, IPS is more suitable to view dynamic images such as cricket and can entirely satisfy consumer needs for high definition images.

Cricket mania in India has undeniably turned the sport into a large industry in the country. With the LG LED LCDs backed by IPS technology, the viewing experience is further enhanced. With the advantages that the technology offers, fast moving pictures are best seen on IPS LCD TVs. Viewers tend to watch TV sports matches together with their families. However, the atmosphere

We all want to watch dynamic pictures of TV programmes and games. The VA LCD has many poor quality pictures. To satisfy consumers with this issue, the image sticking must be solved. Practically, this is the strong point of the IPS panel.

LGs IPS technology backed TVs are indeed the choice of the times. The technology was applied early in some professional sectors, with the unanimous welcome of the professionals. Up to now, all of the top LCD products in the world have adopted this technology, including the products of Eizo, NEC and Apple, etc. to meet the requirements of the sectors and professionals with high technical content in the fields of design, medicine, print, space industry, etc. The technology wins professional favours for the following reasons:

- IPS Panel is better than VA Panel in structure, pressure resistance and stability
- The response speed of IPS Panel is 10 times faster than VA one
- More precise color reducibility of IPS panel

IPS PANELS HAVE SEVERAL ADVANTAGES OVER CONVENTIONAL PANELS:

- They enable vivid and clear moving images because of excellent Moving Picture Response Time (MPRT) performance and variation
- There is no colour distortion from any angle because of no shift in gamma rays, thus least strenuous to human eyes
- Touch panel is vastly stable because moving picture image sticking does not occur
- There's premium size advantage, because of larger panels. To exemplify, 42W is 10% larger than 40W, a gap that's equal to 12.1"
